

Spatio-temporal Models

Lecture 23

Dr. Colin Rundel

Spatial Models with AR time dependence

Example - Weather station data

`NETemp.dat` - Monthly temperature data (Celsius) recorded across the Northeastern US starting in January 2000.

Dynamic Linear / State Space Models (time)

$$\underset{1 \times 1}{y_t} = \underset{1 \times p}{F'_t} \underset{p \times 1}{\theta_t} + v_t$$

observation equation

$$\underset{p \times 1}{\theta_t} = \underset{p \times p}{G_t} \underset{p \times 1}{\theta_{t-1}} + \underset{p \times 1}{\omega_t}$$

evolution equation

$$v_t \sim N(0, V_t)$$

$$\omega_t \sim N(0, W_t)$$

DLM vs ARMA

ARMA / ARIMA are special cases of the more general dynamic linear model framework, for example an AR(p) can be written as

$$F'_t = (1, 0, \dots, 0)$$

$$G_t = \begin{pmatrix} \phi_1 & \phi_2 & \cdots & \phi_{p-1} & \phi_p \\ 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & 0 \\ 0 & 0 & \cdots & 1 & 0 \end{pmatrix}$$

$$\omega_t = (\omega_1, 0, \dots, 0), \quad \omega_1 \sim N(0, \sigma^2)$$

$$y_t = \theta_t + v_t$$

$$\theta_t = \sum_{i=1}^p \phi_i \theta_{t-i} + \omega_1$$

$$v_t \sim N(0, \sigma_v^2)$$

$$\omega_1 \sim N(0, \sigma_\omega^2)$$

Dynamic spatio-temporal model

The observed temperature at time t and location s is given by $y_t(s)$ where,

$$y_t(s) = \mathbf{x}_t(s)\boldsymbol{\beta}_t + u_t(s) + \epsilon_t(s)$$

$$\epsilon_t(s) \stackrel{\text{ind}}{\sim} N(0, \tau_t^2)$$

$$\boldsymbol{\beta}_t = \boldsymbol{\beta}_{t-1} + \boldsymbol{\eta}_t$$

$$\boldsymbol{\eta}_t \stackrel{\text{i.i.d.}}{\sim} N(0, \boldsymbol{\Sigma}_\eta)$$

$$u_t(s) = u_{t-1}(s) + w_t(s)$$

$$w_t(s) \stackrel{\text{ind.}}{\sim} N(\mathbf{0}, \Sigma_t(\phi_t, \sigma_t^2))$$

Additional assumptions for $t = 0$,

$$\boldsymbol{\beta}_0 \sim N(\boldsymbol{\mu}_0, \boldsymbol{\Sigma}_0)$$

$$u_0(s) = 0$$

Data and Model Parameters

Data:

```
1 max_d = coords |> dist() |> max()
2 n_t = 24
3 n_s = nrow(ne_temp)
```

Parameters:

```
1 n_beta = 2
2 starting = list(
3   beta = rep(0, n_t * n_beta), phi = rep(3/(max_d/4), n_t),
4   sigma.sq = rep(1, n_t), tau.sq = rep(1, n_t),
5   sigma.eta = diag(0.01, n_beta)
6 )
7 tuning = list(phi = rep(1, n_t))
8 priors = list(
9   beta.0.Norm = list(rep(0, n_beta), diag(1000, n_beta)),
10  phi.Unif = list(rep(3/(0.9 * max_d), n_t), rep(3/(0.05 * max_d), n_t)),
11  sigma.sq.IG = list(rep(2, n_t), rep(2, n_t)),
12  tau.sq.IG = list(rep(2, n_t), rep(2, n_t)),
13  sigma.eta.IW = list(2, diag(0.001, n_beta))
14 )
```

Fitting with spDynLM from spBayes

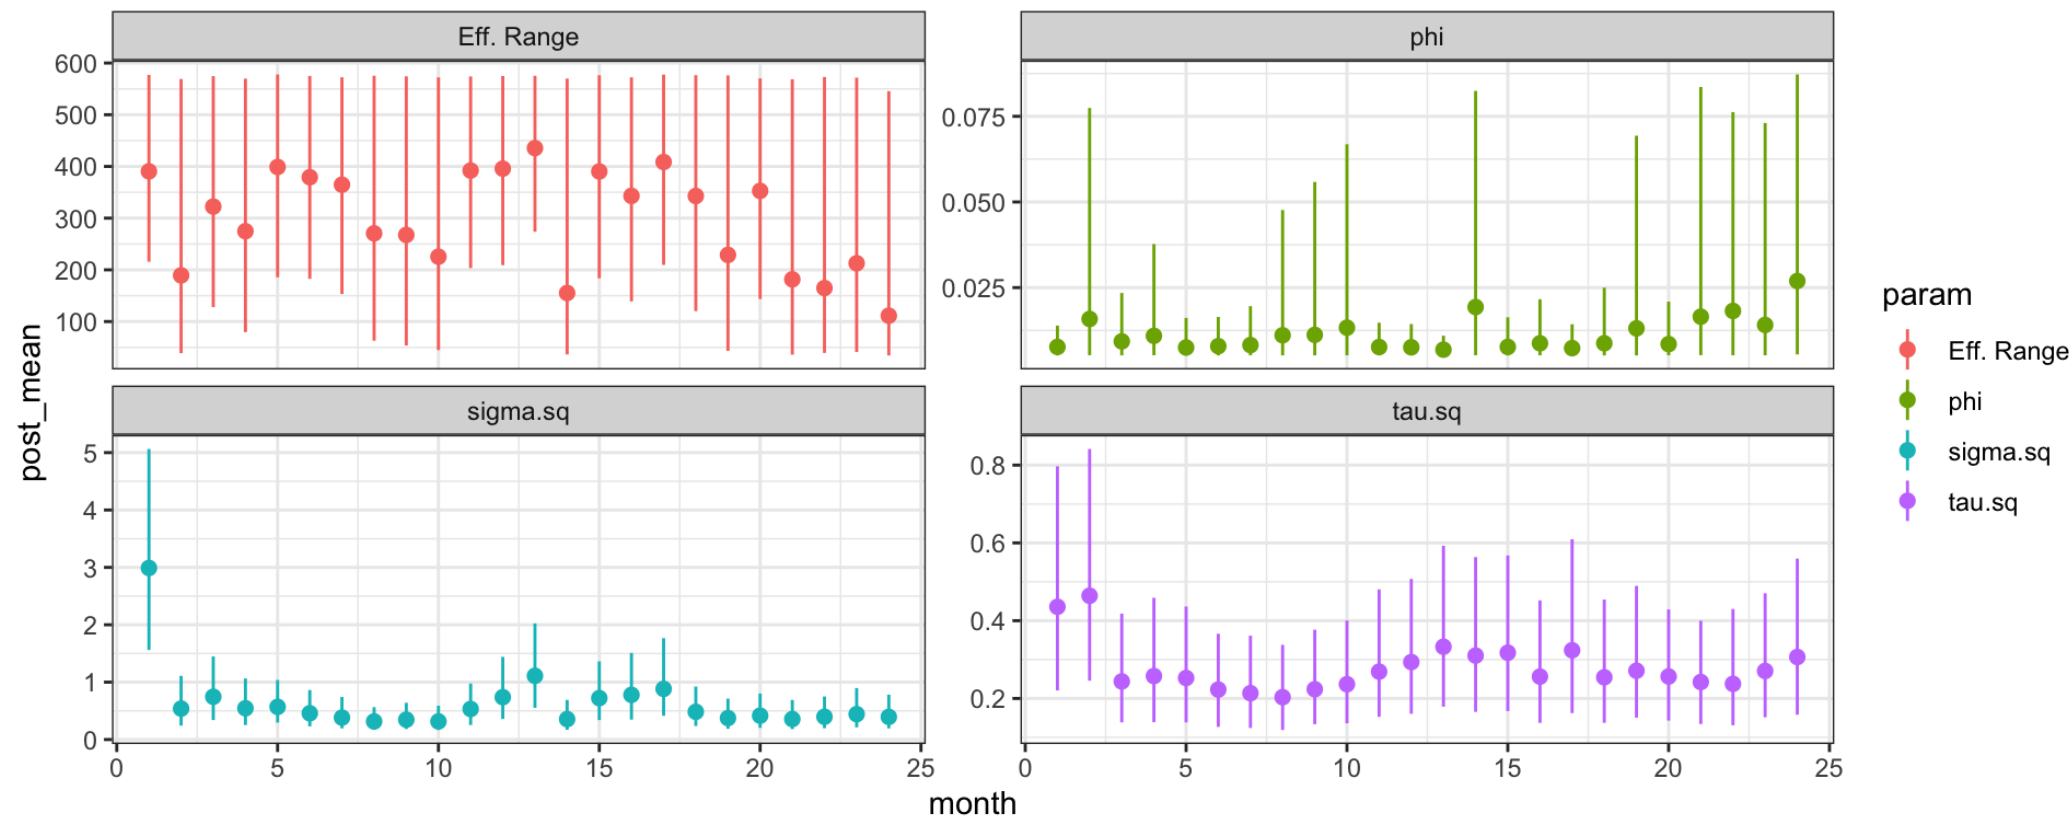

```
1 n_samples = 10000
2 models = lapply(paste0("t_",1:24, "~elev"), as.formula)
3
4 m = spBayes::spDynLM(
5   models, data = ne_temp, coords = coords, get.fitted = TRUE,
6   starting = starting, tuning = tuning, priors = priors,
7   cov.model = "exponential", n.samples = n_samples, n.report = 1000
8 )
```

```
## -----
##      General model description
## -----
## Model fit with 34 observations in 24 time steps.
##
## Number of missing observations 0.
##
## Number of covariates 2 (including intercept if specified).
##
## Using the exponential spatial correlation model.
##
## Number of MCMC samples 10000.
##
## ...
```

Posterior Inference - β s

Posterior Inference - θ

Posterior Inference - Observed vs. Predicted

Prediction

`spPredict` does not support `spDynLM` objects but `spDynLM` will impute missing values.

```
1 r = raster(xmn=5750, xmx=6300, ymn=3000, ymx=3550, nrow=20, ncol=20)
2
3 pred = bind_rows(
4   ne_temp |> mutate(type = "obs"),
5   xyFromCell(r, 1:length(r)) |>
6     as.data.frame() |>
7     mutate(type="pred")
8 )
```

```

1 models_pred = lapply(paste0("t_", 1:n_t, "~1"), as.formula)
2
3 n_samples = 5000
4 m_pred = spBayes::spDynLM(
5   models_pred, data = pred, coords = coords_pred, get.fitted = TRUE,
6   starting = starting, tuning = tuning, priors = priors,
7   cov.model = "exponential", n.samples = n_samples, n.report = 1000)

```

```

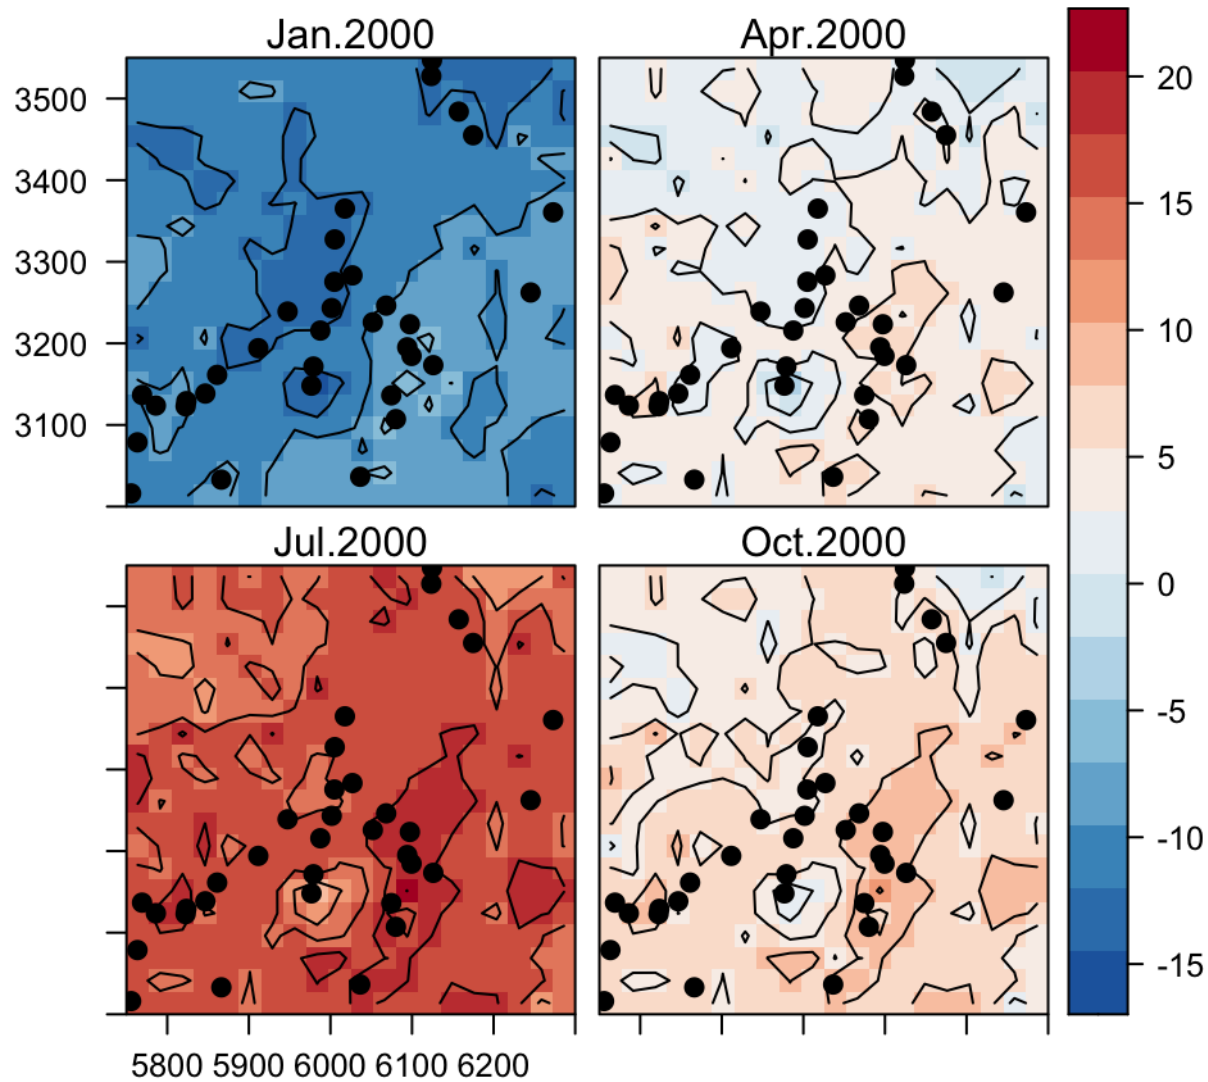

## -----
## General model description
## -----
## Model fit with 434 observations in 24 time steps.
##
## Number of missing observations 9600.
##
## Number of covariates 1 (including intercept if specified).
##
## Using the exponential spatial correlation model.
##
## Number of MCMC samples 5000.
##
## ...

Spatio-temporal models for continuous time

Additive Models

In general, spatiotemporal models will have a form like the following,

$$\begin{aligned} y(\mathbf{s}, t) &= \underbrace{\mu(\mathbf{s}, t)}_{\text{mean structure}} + \underbrace{e(\mathbf{s}, t)}_{\text{error structure}} \\ &= \underbrace{\mathbf{x}(\mathbf{s}, t) \boldsymbol{\beta}(\mathbf{s}, t)}_{\text{Regression}} + \underbrace{w(\mathbf{s}, t)}_{\text{Spatiotemporal RE}} + \underbrace{\epsilon(\mathbf{s}, t)}_{\text{White Noise}} \end{aligned}$$

The simplest possible spatiotemporal model is one where we assume there is no dependence between observations in space and time,

$$w(\mathbf{s}, t) = \alpha(t) + \omega(\mathbf{s})$$

these are straight forward to fit and interpret but are quite limiting (no shared information between space and time).

Spatiotemporal Covariance

Lets assume that we want to define our spatiotemporal random effect to be a single stationary Gaussian Process (in 3 dimensions^{*}),

$$\mathbf{w}(s, t) \sim N(\mathbf{0}, \mathbf{\Sigma}(s, t))$$

where our covariance function will depend on both $\|s - s'\|$ and $|t - t'|$,

$$\text{cov}(\mathbf{w}(s, t), \mathbf{w}(s', t')) = c(\|s - s'\|, |t - t'|)$$

- Note that the resulting covariance matrix will be of size $n_s \cdot n_t \times n_s \cdot n_t$.
 - Even for modest problems this gets very large (past the point of direct computability).
 - If $n_t = 52$ and $n_s = 100$ we have to work with a 5200×5200 covariance matrix

Separable Models

One solution is to use a separable form, where the covariance is the product of a valid 2d spatial and a valid 1d temporal covariance function,

$$\text{cov}(\mathbf{w}(s, t), \mathbf{w}(s', t')) = \sigma^2 \rho_1(\|s - s'\|; \boldsymbol{\theta}) \rho_2(|t - t'|; \boldsymbol{\phi})$$

If we define our observations as follows (stacking time locations within spatial locations)

$$\mathbf{w}(\mathbf{s}, \mathbf{t}) = \left(w(\mathbf{s}_1, t_1), \dots, w(\mathbf{s}_1, t_{n_t}), \dots, w(\mathbf{s}_{n_s}, t_1), \dots, w(\mathbf{s}_{n_s}, t_{n_t}) \right)^t$$

then the covariance can be written as

$$\underset{n_s n_t \times n_s n_t}{\boldsymbol{\Sigma}_w(\sigma^2, \theta, \phi)} = \sigma^2 \underset{n_s \times n_s}{\mathbf{H}_s(\theta)} \otimes \underset{n_t \times n_t}{\mathbf{H}_t(\phi)}$$

where $\mathbf{H}_s(\theta)$ and $\mathbf{H}_t(\theta)$ are correlation matrices defined by

$$\begin{aligned} \{\mathbf{H}_s(\theta)\}_{ij} &= \rho_1(\|\mathbf{s}_i - \mathbf{s}_j\|; \theta) \\ \{\mathbf{H}_t(\phi)\}_{ij} &= \rho_2(|t_i - t_j|; \phi) \end{aligned}$$

Kronecker Product

Definition:

$$\underset{[m \times n]}{\mathbf{A}} \otimes \underset{[p \times q]}{\mathbf{B}} = \underset{[m \cdot p \times n \cdot q]}{\begin{pmatrix} a_{11}\mathbf{B} & \cdots & a_{1n}\mathbf{B} \\ \vdots & \ddots & \vdots \\ a_{m1}\mathbf{B} & \cdots & a_{mn}\mathbf{B} \end{pmatrix}}$$

Properties:

$$\begin{aligned} \mathbf{A} \otimes \mathbf{B} &\neq \mathbf{B} \otimes \mathbf{A} && \text{(usually)} \\ (\mathbf{A} \otimes \mathbf{B})^t &= \mathbf{A}^t \otimes \mathbf{B}^t \end{aligned}$$

$$\begin{aligned} \det(\mathbf{A} \otimes \mathbf{B}) &= \det(\mathbf{B} \otimes \mathbf{A}) \\ &= \det(\mathbf{A})^{\text{rank}(\mathbf{B})} \det(\mathbf{B})^{\text{rank}(\mathbf{A})} \end{aligned}$$

$$(\mathbf{A} \otimes \mathbf{B})^{-1} = \mathbf{A}^{-1} \otimes \mathbf{B}^{-1}$$

Kronecker Product and MVN Likelihoods

If we have a spatiotemporal random effect with a separable form,

$$\mathbf{w}(s, t) \sim \mathbf{N}(\mathbf{0}, \mathbf{\Sigma}_w)$$

$$\mathbf{\Sigma}_w = \sigma^2 \mathbf{H}_s \otimes \mathbf{H}_t$$

then the likelihood for \mathbf{w} is given by

$$\begin{aligned} & -\frac{n}{2} \log 2\pi - \frac{1}{2} \log |\mathbf{\Sigma}_w| - \frac{1}{2} \mathbf{w}^t \mathbf{\Sigma}_w^{-1} \mathbf{w} \\ &= -\frac{n}{2} \log 2\pi - \frac{1}{2} \log [(\sigma^2)^{n_t \cdot n_s} |\mathbf{H}_s|^{n_t} |\mathbf{H}_t|^{n_s}] - \frac{1}{2\sigma^2} \mathbf{w}^t (\mathbf{H}_s^{-1} \otimes \mathbf{H}_t^{-1}) \mathbf{w} \end{aligned}$$

Non-seperable Models

- Additive and separable models are still somewhat limiting
- Cannot treat spatiotemporal covariances as 3d observations
- Possible alternatives:
 - Specialized spatiotemporal covariance functions, i.e.

$$\gamma(\mathbf{s}, \mathbf{s}', t, t') = \sigma^2 (|t - t'| + 1)^{-1} \exp \left(- \|\mathbf{s} - \mathbf{s}'\| (|t - t'| + 1)^{-\beta/2} \right)$$

- Mixtures of separable covariances, i.e.

$$w(\mathbf{s}, t) = w_1(\mathbf{s}, t) + w_2(\mathbf{s}, t)$$
