## Linear Models

Lecture 02

Dr. Colin Rundel

#### **Linear Models Basics**

Pretty much everything we a going to see in this course will fall under the umbrella of either linear or generalized linear models.

In previous classes most of your time has likely been spent with the *iid* case,

$$y_i = \beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip} + \epsilon_i$$
$$\epsilon_i \stackrel{iid}{\sim} N(0, \sigma^2)$$

these models can also be expressed as,

$$y_i \stackrel{\text{iid}}{\sim} N(\beta_0 + \beta_1 x_{i1} + \dots + \beta_p x_{ip}, \sigma^2)$$

#### Some notes on notation

- Observed values and scalars will usually be lower case letters, e.g.  $x_i, y_i, z_{ij}.$
- Parameters will usually be greek symbols, e.g.  $\mu$ ,  $\sigma$ ,  $\rho$ .
- Vectors and matrices will be shown in bold, e.g.  $\mu, X, \Sigma$ .
- Elements of a matrix (or vector) will be referenced with {}s, e.g.  ${\{Y\}}_i, {\{\Sigma\}}_{ij}$
- Random variables will be indicated by  $\sim$ , e.g.  $x \sim Norm(0, 1), z \sim Gamma(1, 1)$
- Matrix / vector transposes will be indicated with ', e.g. A', (1 B)'

#### Linear model - matrix notation

We can also express a linear model using matrix notation as follows,

$$Y = X \beta + \epsilon$$

$$n \times 1 = n \times p p \times 1 = n \times 1$$

$$\epsilon_{n \times 1} \sim N(0, \sigma^2 1_n)$$

$$n \times 1 = n \times 1$$

or alternatively as,

$$\mathbf{Y}_{n\times 1} \sim N \left( \mathbf{X}_{n\times p} \mathbf{\beta}_{p\times 1}, \sigma^2 \mathbb{1}_n \right)$$

#### Multivariate Normal Distribution - Review

For an n-dimension multivate normal distribution with covariance  $\Sigma$  (positive semidefinite) can be written as

$$\mathbf{Y}_{n\times 1} \sim N(\boldsymbol{\mu}, \boldsymbol{\Sigma}_{n\times n})$$

where 
$$\left\{\boldsymbol{\Sigma}\right\}_{ij}=\rho_{ij}\sigma_{i}\sigma_{j}$$

$$\begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} \sim N \begin{pmatrix} \begin{pmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_n \end{pmatrix}, \begin{pmatrix} \rho_{11}\sigma_1\sigma_1 & \rho_{12}\sigma_1\sigma_2 & \cdots & \rho_{1n}\sigma_1\sigma_n \\ \rho_{21}\sigma_2\sigma_1 & \rho_{22}\sigma_2\sigma_2 & \cdots & \rho_{2n}\sigma_2\sigma_n \\ \vdots & \vdots & \ddots & \vdots \\ \rho_{n1}\sigma_n\sigma_1 & \rho_{n2}\sigma_n\sigma_2 & \cdots & \rho_{nn}\sigma_n\sigma_n \end{pmatrix}$$

### **Multivariate Normal Distribution - Density**

For the n dimensional multivate normal given on the last slide, its density is given by

$$f(\boldsymbol{Y}|\boldsymbol{\mu},\boldsymbol{\Sigma}) = (2\pi)^{-n/2} \det(\boldsymbol{\Sigma})^{-1/2} \exp\left(-\frac{1}{2}(\boldsymbol{Y}-\boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\boldsymbol{Y}-\boldsymbol{\mu})\right)$$

and its log density is given by

$$\log f(\mathbf{Y}|\boldsymbol{\mu}, \boldsymbol{\Sigma}) = -\frac{n}{2}\log 2\pi - \frac{1}{2}\log \det(\boldsymbol{\Sigma}) - \frac{1}{2}(\mathbf{Y}-\boldsymbol{\mu})' \boldsymbol{\Sigma}^{-1} (\mathbf{Y}-\boldsymbol{\mu})$$

#### Some useful matrix identities

The following come from the Matrix Cookbook Chapters 1 & 2.

$$(AB)' = B'A'$$

$$(A + B)' = A' + B'$$

$$(A')^{-1} = (A^{-1})'$$

$$(ABC ...)^{-1} = ... C^{-1}B^{-1}A^{-1}$$

$$\det(A') = \det(A)$$

$$\det(AB) = \det(A)$$

$$\det(A') = \det(A)$$

## Maximum Likelihood - $\beta$ (iid)

## Maximum Likelihood - $\sigma^2$ (iid)

## A Quick Example

### Parameters -> Synthetic Data

Lets generate some simulated data where the underlying model is known and see how various regression procedures function.

$$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \epsilon_i$$
 $\epsilon_i \sim N(0, 1)$ 
 $\beta_0 = 0.7, \ \beta_1 = 1.5, \ \beta_2 = -2.2, \ \beta_3 = -2.2$ 

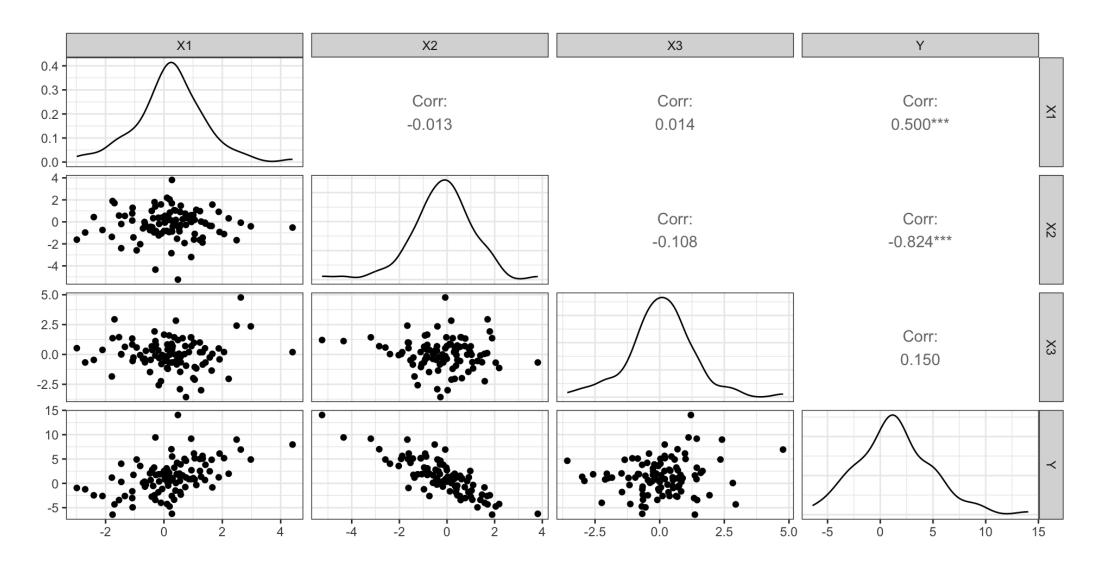

```
1  set.seed(1234)
2  n = 100
3  beta = c(0.7, 1.5, -2.2, 0.1)
4  sigma = 1
5  eps = rnorm(n, 0, sd = sigma)
6
7  d = data_frame(
8     X1 = rt(n,df=5),
9     X2 = rt(n,df=5),
10     X3 = rt(n,df=5)
11  ) |>
12  mutate(
13     Y = beta[1] + beta[2]*X1 + beta[3]*X2 + k
14  )
```

#### **Model Matrix**

```
1 X = model.matrix(~X1+X2+X3, d)
 2 tbl df(X)

## Pairs plot

```
1 GGally::ggpairs(d, progress = FALSE)
```

## Least squares fit

Let  $\hat{Y}$  be our estimate for Y based on our estimate of  $oldsymbol{eta}$ ,

$$\hat{\mathbf{Y}} = \hat{\beta_0} + \hat{\beta_1} \, \mathbf{X}_1 + \hat{\beta_2} \, \mathbf{X}_2 + \hat{\beta_3} \, \mathbf{X}_3 = \mathbf{X} \, \hat{\boldsymbol{\beta}}$$

The least squares estimate,  $\hat{m{\beta}_{1s}}$ , is given by

$$\hat{\boldsymbol{\beta}}_{ls} = \underset{\boldsymbol{\beta}}{\operatorname{argmin}} \sum_{i=1}^{n} (Y_i - \boldsymbol{X}_{i\cdot}\boldsymbol{\beta})^2$$

Previously we showed that,

$$\hat{\boldsymbol{\beta}}_{1s} = (\boldsymbol{X}'\boldsymbol{X})^{-1}\boldsymbol{X}'\boldsymbol{Y}$$

#### Beta estimate

```

```

# Bayesian regression model

### **Basics of Bayes**

We will be fitting the same model as described above, we just need to provide some additional information in the form of a prior for our model parameters (the  $\beta$ s and  $\sigma^2$ ).

$$f(\theta|\mathbf{x}) = \frac{f(\mathbf{x}|\theta) \pi(\theta)}{\int f(\mathbf{x}|\theta) d\theta}$$
$$\propto f(\mathbf{x}|\theta) \pi(\theta)$$

#### brms

We will be using a package called brms for most of our Bayesian model fitting

- it has a convenient model specification syntax
- mostly sensible prior defaults
- supports most of the model types we will be exploring
- uses Stan behind the scenes

## brms + linear regression

```
1 b = brms::brm(Y \sim X1 + X2 + X3, data=d, chains = 2, silent = 2)

```
(pt est = post sum |>
     filter(.chain == 1) |>
     ungroup() |>
     mutate(
     truth = c(beta, sigma),
 6
       ols = c(l$coefficients,
                 sd(l$residuals))
     ) |>
     select(
       .variable, truth,
10
11
       ols, post mean
12
13 )
```

### **Comparing Approaches**

```
post |>
filter(.chain == 1) |>
ggplot(aes(x=.value)) +
geom_density(alpha=0.5, fill="lightblue") +
facet_wrap(~.variable, scale="free_x") +
geom_vline(
data = pt_est |> tidyr::pivot_longer(cols = truth:post_mean, names_t
aes(xintercept = value, color=pt_est),
alpha = 0.5, size=1.5
```
